Problem: The type-attribute of the entry-element is overloaded with three different kinds of information: "begin/end", "stop/pass", "operational/conditional".

The RhB (Rhätische Bahn) uses railML to distribute timetable information between their systems and need a more detailed distinction for the different kinds of stop.

As further development of the timetable schema I therefore suggest to delete the two enumerations "operational" and "conditional" of the attribute "type" and use a new (optional) element "stopDescription" instead, with the following attributes (all optional):

- commercial            boolean Indicates, whether the stop is for commercial purpose (announced to customer) or operational only.
- stopOnRequest        boolean Indicates, whether the train stops always or on request only. Typically in combination with minStopTime = 0.
- onOff                on/off/both    Indicates, whether passengers are allowed to get on or off the train and goods may be loaded or unloaded.
- purpose             string            Describes the purpose of the stop.  
(e.g. crew change, customs)
- serviceID            string            Train stops on specified days only. (Seasonal Stop)

I think this covers most of the different kinds of stops.

Joachim
