Hello,

after version 2.0 I have introduced the element <tilting> with its attributes "actuation", "maxTiltingAngle" and "tiltingSpeed".

With the new SBB twin deck trains for IC use the was a new kind of tilting - the roll compensation (Wankkompensation). Now its the question whether there is the need for any revision of this element in order to name all important data of such a system.

Please provide any ideas.

The Wankkompensation can be used as a kind of tilting system. Tilting systems as used in Germany tilt the body of the car to bring the lateral acceleration down. The system used for SBB keeps the body of the waggon in a vertical position which is especially required for double deck coaches. So the tilting angle caused by the suspension is reset to zero with help of the roll compensation.

At the end no other elements or attributes are required to describe roll compensation.

Best regards.

Carsten

The 'rollCompensation' can now be selected as type of tilting actuation,  
i.e. none/active/passive/rollCompensation.
